• Objective of the analysis

The objective of this analysis is to be able to define a model to predict if a patient can have an heart attack based on some heart parameters

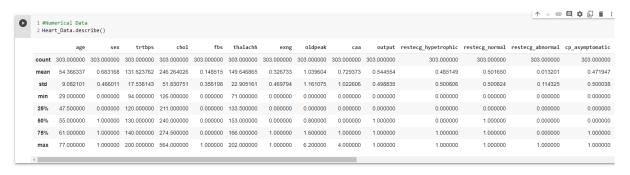

· Description of the data set

For this project I'm going to use a Data Set representing Heart Attack classification. Each case of heart attack has some parameters:

- 1. age age in years
- 2. sex sex (1 = male; 0 = female)
- 3. cp chest pain type (1 = typical angina; 2 = atypical angina; 3 = non-anginal pain; 0 = asymptomatic)
- 4. trestbps resting blood pressure (in mm Hg on admission to the hospital)
- 5. chol serum cholesterol in mg/dl
- 6. fbs fasting blood sugar > 120 mg/dl (1 = true; 0 = false)
- 7. restecg resting electrocardiographic results (1 = normal; 2 = having ST-T wave abnormality; 0 = hypertrophy)
- 8. thalach maximum heart rate achieved
- 9. exang exercise induced angina (1 = yes; 0 = no)
- 10. oldpeak ST depression induced by exercise relative to rest
- 11. slope the slope of the peak exercise ST segment (2 = upsloping; 1 = flat; 0 = downsloping)
- 12. ca number of major vessels (0-3) colored by fluoroscopy
- 13. thal 2 = normal; 1 = fixed defect; 3 = reversible defect
- 14. num the predicted attribute diagnosis of heart disease (angiographic disease status)

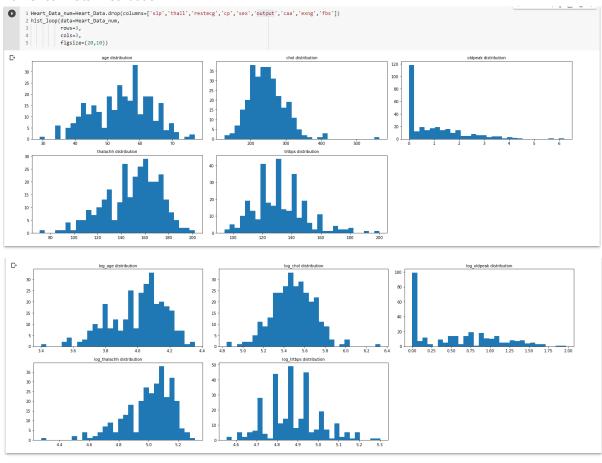

(Value 0 = < diameter narrowing; Value 1 = > 50% diameter narrowing)

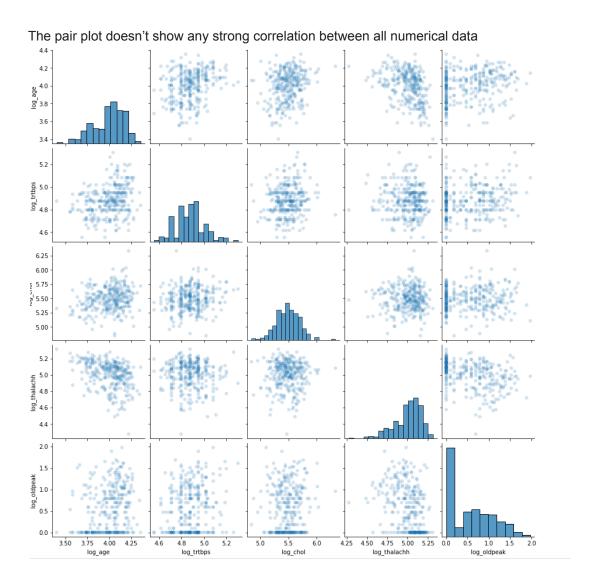

Data Describe

Numerical Data

Numerical Data Distribution.

• Train / Test Split

As first step we proceed to split the dataset in Train and Test Split and the using a k-fold cross validation in order to prevent overfitting.

```
11 #K-Fold
12 kf = KFold(shuffle=True, random_state=72018, n_splits=3)
```

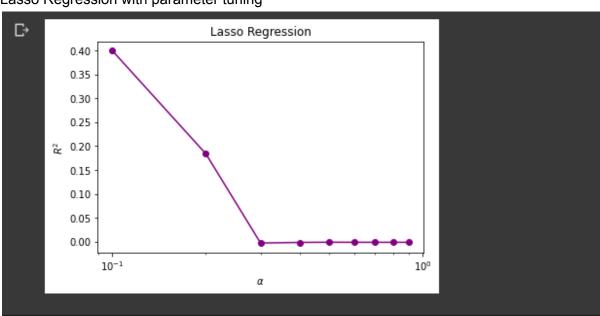

• Finding The Best Model

Now we proceed to test some regression model to find witch better perform with our data set

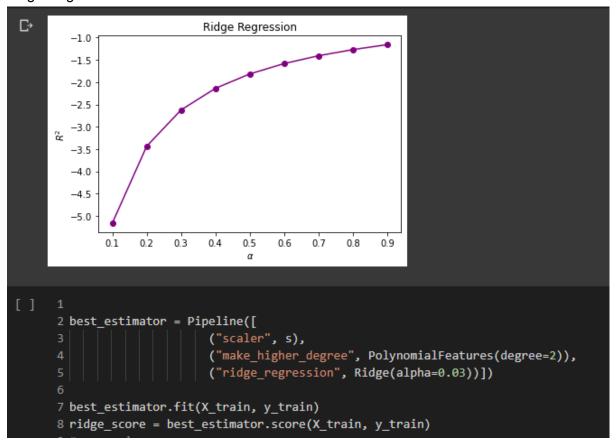

Basic Regression

```
1 from sklearn.metrics import r2_score, mean_squared_error
2 #Linear Regression
3 # vanilla regression and K-fold cross validation
4 s = StandardScaler()
5 lr = LinearRegression()
7 X train s = s.fit transform(X train)
8 lr.fit(X_train_s, y_train)
9 X_test = s.transform(X_test)
10 y pred = lr.predict(X test)
11 score = r2_score(y_test.values, y_pred)
12
13 # with pipeline
14 estimator = Pipeline([("scaler", s),("regression", lr)])
15 predictions_lr = cross_val_predict(estimator, X_train, y_train, cv=kf)
16 linear_score = r2_score(y_train, predictions_lr)
18 linear_score, score #almost identical
```

Lasso Regression with parameter tuning

Ridge Regression

Final Thoughts

score 0.48	9702	0.6422	254	0.899014

Due to the high number of parameters the ridge regression performs better in estimate . Probably this is more a classification problem so another algorithm can get more precise and significative resultis
